A1 Study Description

The microgrids were installed and data collected in Barabanki district in Uttar Pradesh state in India. In total, 49 habitations are included in the study. These 49 habitations were all non-electrified in the beginning of the study; all electrified habitations were removed from the sample before the random assignment of solar microgrids.

The timeline of the study runs as follows:

1. In February 2014, a baseline survey of study households was conducted.
2. Between February-July 2014, solar microgrids were offered to all habitations ($N = 49$).
3. In August 2014, a special “summer survey” of MGP subscribers at the time was conducted to assess customer experience and satisfaction.
4. In October 2014, a midline survey of the study households was conducted.
5. In June 2015, an endline survey of the study households was conducted.

For the baseline survey, a random sample of 16 households per habitation were interviewed. The 16 households were sampled within a 100-meter radius of the center of the habitation. The center of the habitation was defined as a concrete structure that would enable MGP to install a solar microgrid. As the patterns of technology adoption among the survey respondents show, this strategy performed well in ensuring that we surveyed households that would be able to adopt solar technology as provided by the MGP.

The survey lasted about 45 minutes and was conducted in Hindi by experienced enumerators. One member of the research team trained the enumerators and supervised data collection for each of the survey rounds. The survey included basic socio-economic information, detailed information about energy use and expenditures, as well as questions about perceptions, including risk aversion and entrepreneurial spirit. In the baseline and endline surveys, the goal was to interview the same person in each household that was interviewed in the baseline. If that person was not available for an entire day, another adult from the same household was interviewed. If the entire household was away or had migrated out, a replacement household was found.

The solar microgrid installation process began with entry into village by the MGP team. The team provided households in the habitation an opportunity to subscribe to the off-grid solar electricity service. The team offered the service both to households in our survey (16 for each habitation) and other households outside the survey. Households did not have to commit to the service; they were free to discontinue the subscription at any time. However, the households had to pay the 100 rupee monthly charge in advance. If MGP secured at least 10 subscriptions, a microgrid was installed. If there were fewer subscriptions, the microgrid was not installed.

While MGP attempted to install solar microgrids in 54 habitations, the installation failed in five habitations because of flooding. We do not include these habitations in the study because the households never had the possibility to adopt the solar technology. While the original field experiment described in Aklin et al. (2017) also uses additional habitations without solar microgrid installation as a control group, these habitations are not used in our study because without an MGP offer, households could not possibly adopt the solar technology.

Besides the surveys, we collected data from MGP on the solar microgrid installations. When a microgrid was installed, we sent an independent enumerator to verify that the installation was successful. In the end, we were able to verify that microgrid installation succeeded in 25 out of the 49 habitations in the study.

A2 Map of Study Setting

Figure A1: Locations of our 49 study habitations in Barabanki district and slightly outside it.

A3 Summary Statistics and Data Description

This section provides summary statistics, also disaggregated by adoption status at the habitation and household level.

- Table A1 shows summary statistics for all explanatory variables (pre-treatment) for the full sample.
- Tables A2 and A3 show summary statistics separately for adopting and non-adopting households in habitations in which MGP service was installed.
- Table A4 shows summary statistics for habitations without MGP service.
- Table A6 shows technology adoption by habitation and survey wave; it also provides information on habitation caste composition.

Summary statistics, full sample

	Mean	SD	Min	Max	#
HH expenditures (rupees/month, log)	8.24	0.54	6	10	778

Table A6: MGP adoption by habitation and survey wave. Column (4) shows whether MGP service was installed and column (5) shows the number of surveyed households, with two values indicating midline/endline counts (if different). Column (6) provides caste information where the first and second number is the count of scheduled caste ('S') and backward caste ('B') household heads; numbers do *not* have to sum to the number of total survey households as some households fall in the 'other' category. Columns (7)-(10) show the number/share of adopting households by wave.

A6 Regression Results: Village Fixed-Effects Models

This section shows estimation results for the same set of models as presented in the paper’s results section, while adding village fixed-effects. In the main text, we discussed that habitation fixed effects are problematic in our case as these are likely to introduce bias as all habitations are dropped from the estimation in which either no microgrid was installed (24 habitations) or where microgrids were installed but we did not end up having MGP customers in our random sample of survey respondents (5 habitations).

Nonetheless, to address concerns about spatial heterogeneity, we introduced village level fixed-effects here and re-estimated our main models. The village level is India’s administrative division above the habitation level and hence useful for the purpose of controlling for unobserved (spatial) heterogeneity. Our 49 habitations are clustered in 33 villages.

Logistic regressions: Technology adoption, village fixed-effects
